

There are several technologies that allow you to connect to the internet through an Internet Service Provider (ISP). Here are three different technologies:

- **DSL (Digital Subscriber Line):** DSL is a widely used technology that provides internet access over existing telephone lines. It operates on a frequency band that allows both voice and data transmission simultaneously. DSL can offer varying speeds depending on your location and the quality of the copper telephone lines, with ADSL (Asymmetric DSL) and VDSL (Very-high-bit-rate DSL) being common variants.
- **Cable Modem:** Cable internet uses the same coaxial cable infrastructure that delivers cable television. It provides high-speed internet access by transmitting data over these coaxial cables. Cable internet tends to offer higher speeds compared to DSL and is widely available in many urban and suburban areas.
- **Fiber Optic:** Fiber optic internet uses thin strands of glass or plastic fiber to transmit data as pulses of light. It is known for its incredibly fast and reliable internet connections, often offering symmetrical upload and download speeds. Fiber-optic networks are expanding, but availability may be limited in some regions due to the cost of infrastructure deployment.
